It would be nice to add parameters to subnets in Foreman, and use those parameters to perform certain operations.

I have a concrete case where I want to put every subnet in a given firewall zone (public, internal, dmz, etc.). This means in practice the addition of a ZONE=public line in the ifcfg-file (on RedHat), and firewalld picks it up automatically.

This code will add a function to lookup a subnet parameter by name, and returns it's value. It will return 'nil' if no value was found.

The function is added to the renderer, so it can be called from provisioning templates.
